I create a new ComReference and set a few properties in order to create my object. I then call a method on the object and store the result in a string. I can't seem to figure out how to cast the string to the actual object type. I know that I can use the Type keyword to get the type of the object and cast accordingly, but this fails if the type doesn't exist. Is there a way I can cast the string to the COM object's type? A: You can use the GetObject function to get a reference to the object and the GetType function to get the type of the object. I can't see the code. How is this being done? A: x is a reference to an int, so it is the address of the int. So when you pass x as an argument to Foo it's a reference to an int. Then Foo receives a ce6e30c18e

Clients were also less likely to use their welfare benefits to purchase illicit drugs than before counseling, suggesting that counseling may have benefited both clients and their communities.
